SMARTfit Cloud Architecture on Microsoft Azure

1. The SMARTfit iOS/Android mobile application is configured to work with our Azure App Service for authenticated API calls.
2. Using Azure AD B2C for identity and access management, the Azure App Service receives an access token to authorize requests made to the API.
3. These requests perform operations against the cloud SQL database as the client (mobile application) makes these requests once authenticated.
4. Azure Storage is used to download software update files, app videos, and any other files that need to be used by the mobile application.
5. Predesigned content is pulled to the local SQL database. User data is also pulled from the cloud database to the local database upon sign in and purged upon sign out.
6. The mobile app communicates with the SMARTfit Controller via BLE for all communcation, such as running games, tests, system settings, and software updates.
